On the global scale, urban areas are admonished to increase their food security while reducing CO<sub>2</sub> emissions related to the food supply chain, resulting for instance from transportation or land-use change. In this context, urban and peri-urban agriculture may contribute to an increase in the resilience of the food supply system of cities and to reduce their ecological foot-print. Our work focuses on the carrying capacity of peri-urban areas and on the relative suitability conditions for further development of peri-urban agriculture worldwide. Our analysis builds on a combination of high resolution data on land use, demographics and water availability and agriculture model outputs.
