The radical chemistry of the lower troposphere was investigated during the ZEPTEP-2 field campaign at Lake Constance in October/November 2008, using the unique capabilities of a modified Zeppelin NT as an airborne measurement platform. The Zeppelin was equipped with in-situ instruments for measurement of OH and HO₂ radicals, the main radical precursors (O₃, HONO, HCHO), photolysis frequencies, and prime reactants (NO_x, CO, VOCs) of OH. The instrumentation has been used to chemically characterize the planetary boundary layer and the lower free troposphere. Vertical profiles of the trace gases were observed at altitudes up to 1000m above different land surfaces, including Lake Constance, the city of Ravensburg and forests. In this presentation technical details of the measurement platform Zeppelin NT will be presented as well as first results of the HO_x radical measurements.
