Running head line: Effects of climate change on zooplankton ...

Key words: the Alps, community structure, colonisation, zooplankton, high-altitude lakes, earthquake, climate change

### Abstract

In mesotrophic lake Krnsko jezero (Slovenia), located at tree-line (1383 m a.s.l.) significant changes in zooplankton communities took place after the year 2000. The lake is 17 m deep with a surface of 4.5 ha. Water pH is neutral ( $\text{pH} \geq 7.5$ ), while alkalinity is between 1200 and 2100  $\mu\text{S}$ . In the lake fish (*Salvelinus alpinus* and *Phoxinus phoxinus*) were introduced in 1927 and no manipulation was done afterwards. Survey of fish population indicated low but stable population of *S. alpinus* with a dominance of adult fish. Human activity in the last 30 years was minimal in the watershed of the lake.

The lake Krnsko Jezero is on seismic very active area. In the spring of 1998 strong earthquake hit the area (EMS= 5.6). As a result there was significant change in landscape and increase of nutrients in the water column. However, late-autumn biomass of zooplankton dropped from 2.1 g m<sup>-2</sup> in 1997 to 0.8 g m<sup>-2</sup> in 1998 and has continue to stay low till present. Thermophilic cladoceran, *Ceriodaphnia quadrangula* (filtrator), was for the first time recorded in the lake in 1998, while population of previous dominant cold-water *Cyclops vicinus* (predator) started to decline soon afterward. Six years after earthquake *Cyclops vicinus* completely disappeared from the lake and was completely replaced by *Ceriodaphnia quadrangula*, which is an indication of a change of a trophic status of the lake.

Long term temperature records, 20 years for air-temperature on Kredarica (2600 m a.s.l.; 15 km from the lake) and 9 years for the surface water temperature in the lake Krnsko Jezero, indicate increase of temperature on both locations. A surface temperature of about 20 °C appears to be the threshold for change in zooplankton in the

lake Krnsko Jezero.

As a conclusion we suggest a scenario, where earthquake re-suspended nutrients from the bottom of the lake and at the same time triggered change of zooplankton structure. Cold-water copepod species was replaced by successful colonization of the lake by thermophilic cladoceran species, supported by increased epilimnion temperatures of the lake. Similar scenario, where two cladoceran species were affected by earthquake about 100 years ago and afterward regulated by increased ambiental temperature, was noted from sediment records in a near-by lake Jezero v Ledvicah, too.
