We present the new regional climate simulations over Africa and India made with the latest version of the Regional Climate Model RegCM4 developed in ICTP of Trieste.

We completed two simulations at 50 km of resolution and the ERA- Interim boundary conditions were used from 1990 up to 2009.

With this new version of the model it is possible to use different convection scheme over the ocean and over land, this combination has been used for the Africa domain, where we used Grell scheme over land and MIT-Emanuel over ocean, to be able to have a better representation of the ITCZ for its position and strength. The rainy season during the June-July-August (JJA) over West Africa (Guinea coast and Sahel) shows a bigger improvement when the double scheme is used.

For the India we used Grell scheme everywhere but with different convection parameters over land and over ocean to reduce the precipitation bias over the Indian Ocean.

The model shows a slightly cold bias for the African domain for all the four seasons. The precipitation spatial patters and intensity is reasonably represented for all the seasons with a wet bias over Sahel and Guinea coast and a dry bias over the Congo basin during JJA.

The monsoon precipitation over the Indian continent is reasonably represented and a bigger bias is observed over the ocean close to the African coast. The model shows a slightly cold bias for the JJA season always over the continent.
