Monthly water balance model for climate change analysis in agriculture with R

Kalicz Péter

Summary

Background

Solution

Results

Changing climate and agrarian sector

For Hungary regional climate models projections suggest a warmer climate and some changes in annual precipitation distribution. These changes force the whole agrarian sector to consider the traditional cropping technologies. This situation is more serious in forestry because some forest populations (eg. beech) are on their xeric distributional limits Gálos et al. 2014. Additionally, a decision has an impact sometimes longer than one hundred years.

Monthly water balance model for climate change analysis in agriculture with R

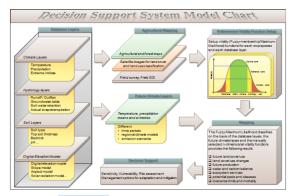

Kalicz Péter

Summary Background Solution

Results

Decision support system

To support the stakeholder there is a project which develops a GIS (Geographic Information System) based decision support system. Hydrology plays significant role in this system because water is often one of the most important limiting factor in Hungary. See Gálos et al. 2014.

Hydrological model calibration

The model is calibrated with the available data between 2000 and 2008. Beside other meteorological data we used mainly an estimated actual evapotranspiration (ET_{actual}) map in the calibration phase, which was derived with the Complementary-relationship-based evapotranspiration mapping (CREMAP) technique Szilágyi and Kovács 2011. ET_{actual} is derived from the MODIS LST composits.

Monthly water balance model for climate change analysis in agriculture with R

Kalicz Péter

Summary

Background

Solution

Results

Choose R

The calibration process is pixel based and it has several stochastic steps.

We try to find a flexible solution for the model implementation which easy to automatize and can be integrate in GIS systems. The open source R programming language was selected which well satisfied these demands.
