

## The FASTNET project

The FASTNet project (Fluxes Across Sloping Topography of the North East Atlantic) aims to elucidate the key processes controlling seasonal, inter-annual and regional variations in ocean-shelf exchange, through a combined strategy of observations and modelling.

In this context, a new 1/60° degree resolution ( $\approx 1.8\text{km}$ ) NEMO configuration has been developed. AMM60 extends on the same domain as the UK Met Office operational Atlantic Margin Model ( $\approx 7\text{km}$ ), enveloping the whole North West European Atlantic margin.

**We evaluate here the capability of this high-resolution configuration to reproduce realistically high frequency processes at the shelf break and on the shelf, focusing principally on the Celtic Sea and the Malin Shelf.**

## AMM60 (Atlantic Margin Model at 1/60°)

### Domain:

- North-West European Atlantic shelf ( $\approx$  same domain as AMM7)
- Regular grid  $\approx 1.8\text{ km}$  (1 nm)
- bathymetry from GEBCO

### Parameterisation:

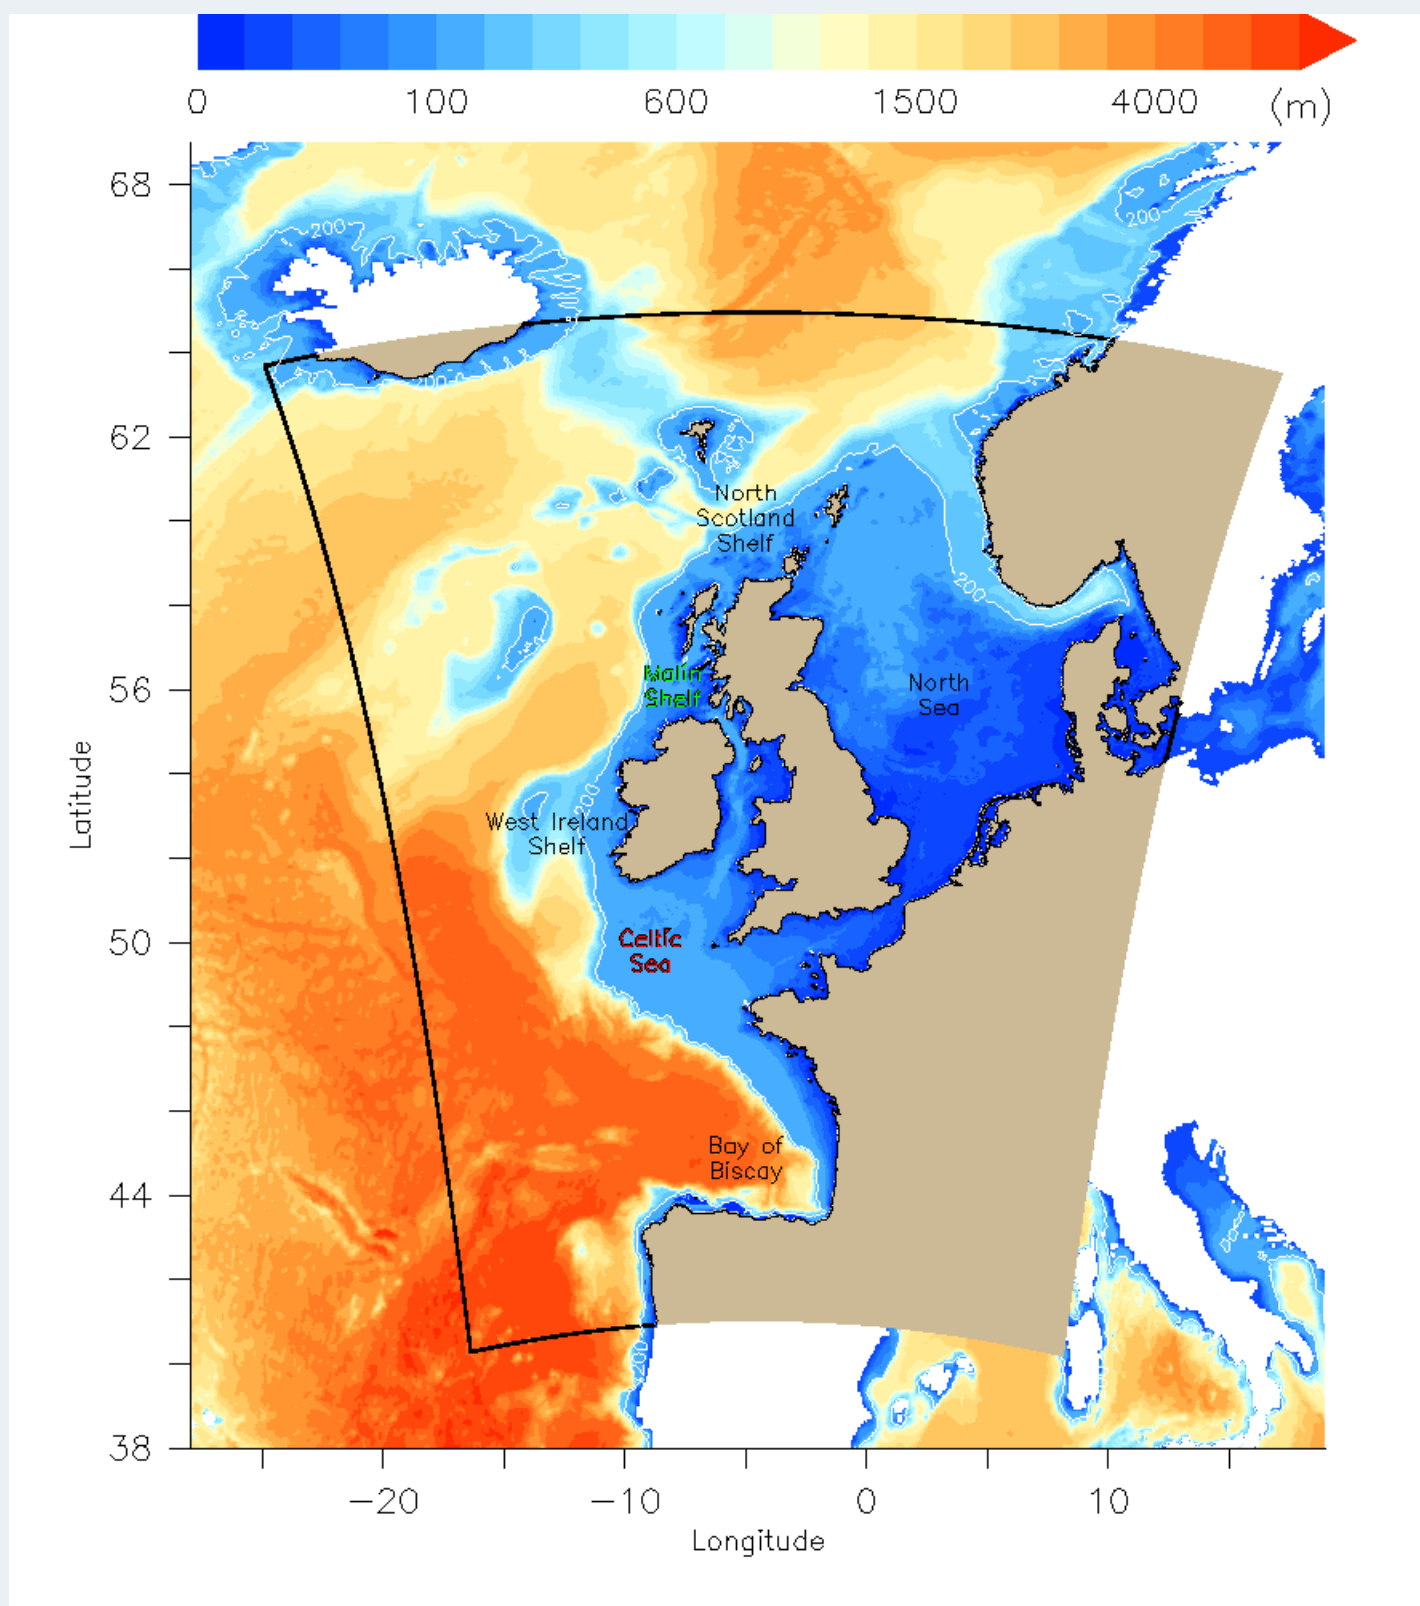

- NEMO 3.6
- 2000 processors
- 51  $\sigma$ -levels
- time-step = 1 minute
- GLS turbulent closure scheme
- TVD advection scheme

### Forcings:

- Surface forcings: ERA-interim (CORE bulk formulation)
- Tidal forcing: TPX07.2
- BDY forcings: NNATL (NEMO, 1/12°)

### Period of simulation:

- 2010 - 2014

Bathymetry of the domain (metres) and key locations. Isobath 200-m is shown in white

## Conclusions on the assessment of AMM60

- Good reproduction of the tides, despite an underestimated amplitude in regions of strong tides
  - How to improve it? Bathymetry, wetting/drying, surface forcing, ...
  - At the moment AMM60 is mostly designed for non-coastal shelf studies, where the tide has the right amplitude
- The SST is in good agreement with satellite data
  - There is a cold bias in the North of the domain, but the same bias is found in NNATL
  - Using a higher-resolution atmospheric forcing could improve the shelf/coastal processes

## Validation of the configuration

### 1) Validation of the tidal amplitude

240 tide gauge measurements of the M2 constituent around the UK.

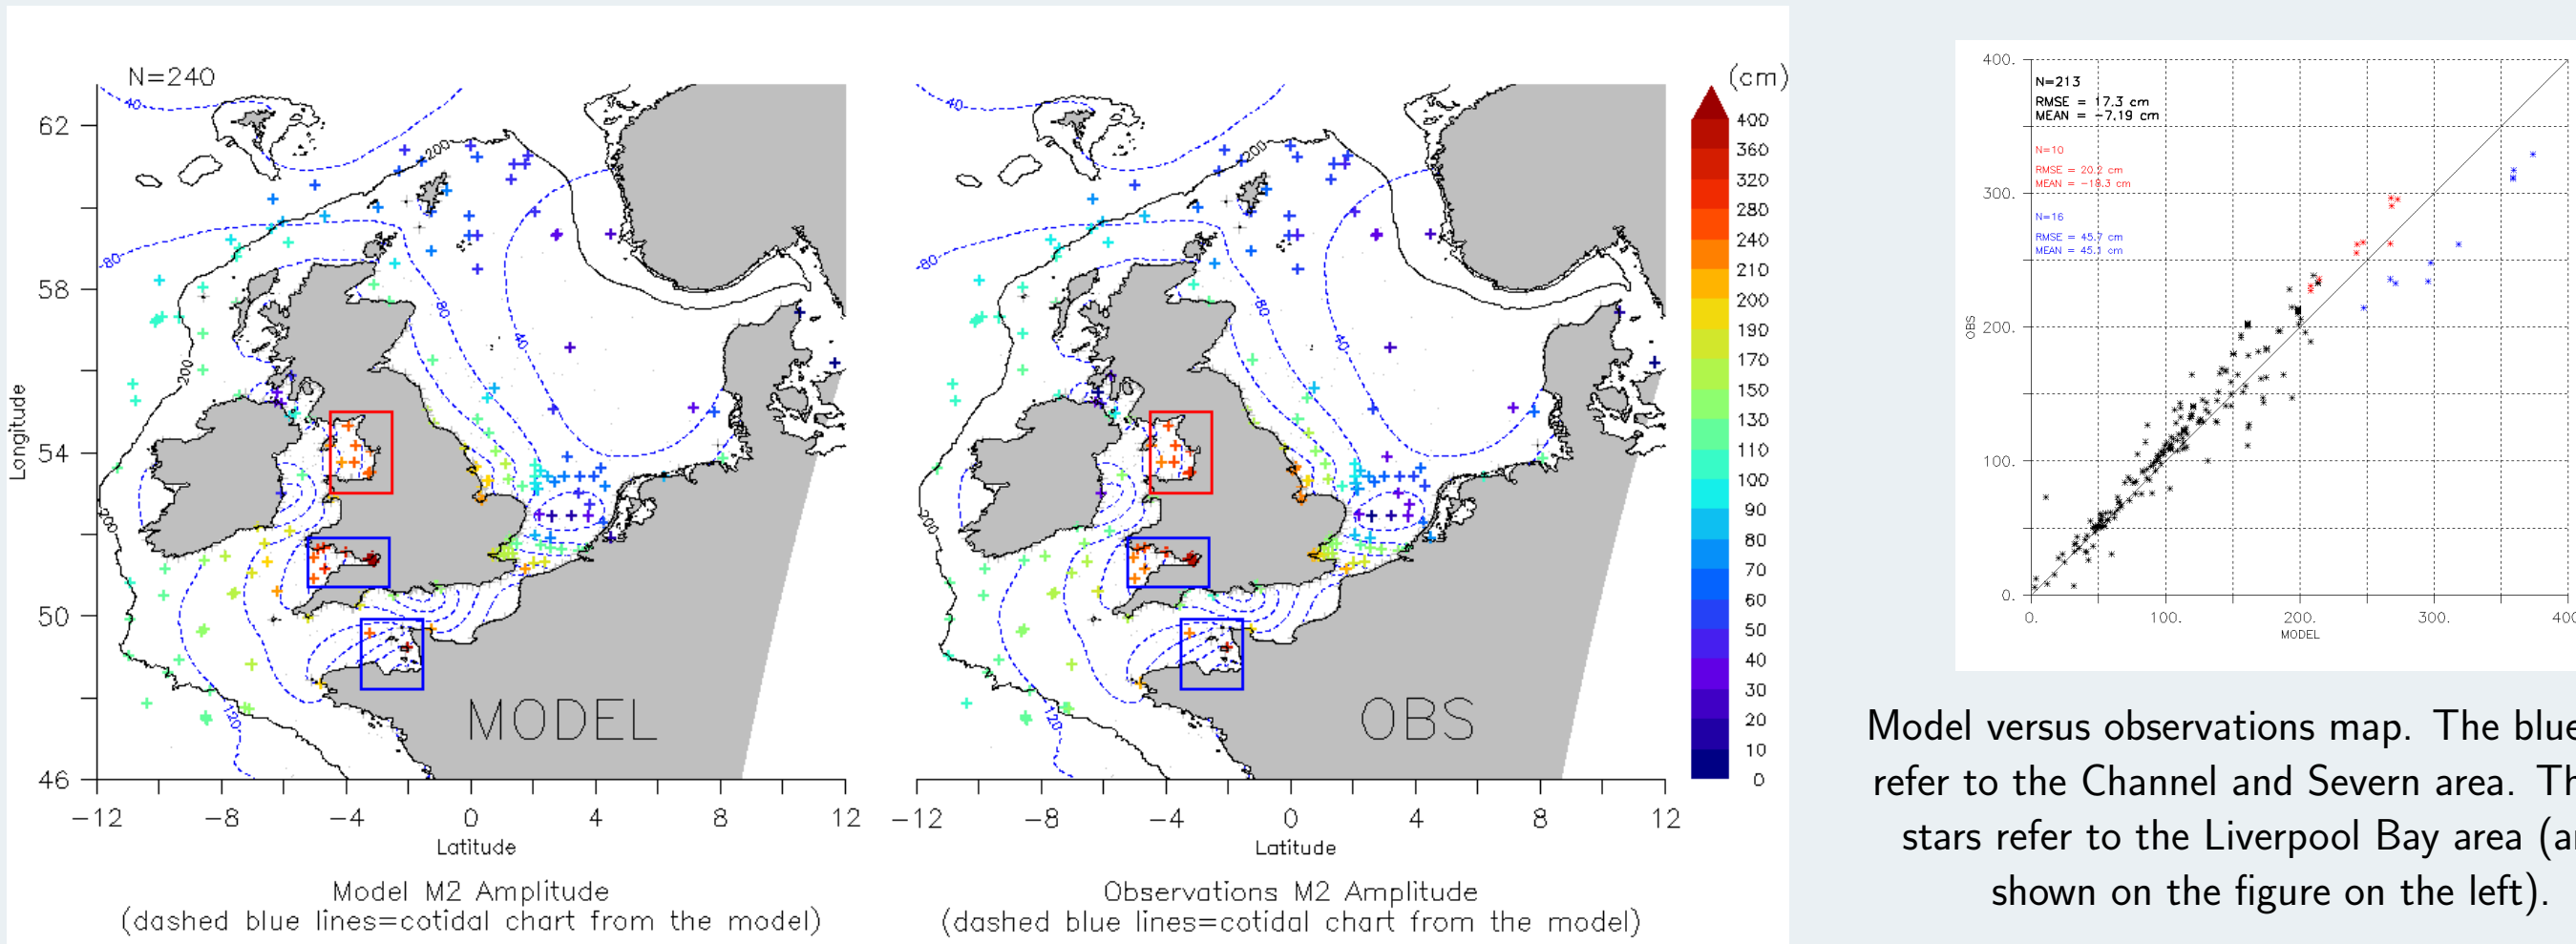

The amplitude of the M2 simulated constituent is in good agreement with tide gauges:

→ small amplitudes in the Irish Sea and the North Sea

→ high amplitudes in the Channel, the Severn and Liverpool Bay

There is a slight overestimation of the amplitude in regions of strong tide (Severn, Channel, in red), but a slight underestimation in Liverpool Bay (in blue).

*AMM60 reproduces correctly the amplitude of the M2 constituent, despite a slight overestimation in regions of strong tides. It is well fit for shelf studies.*

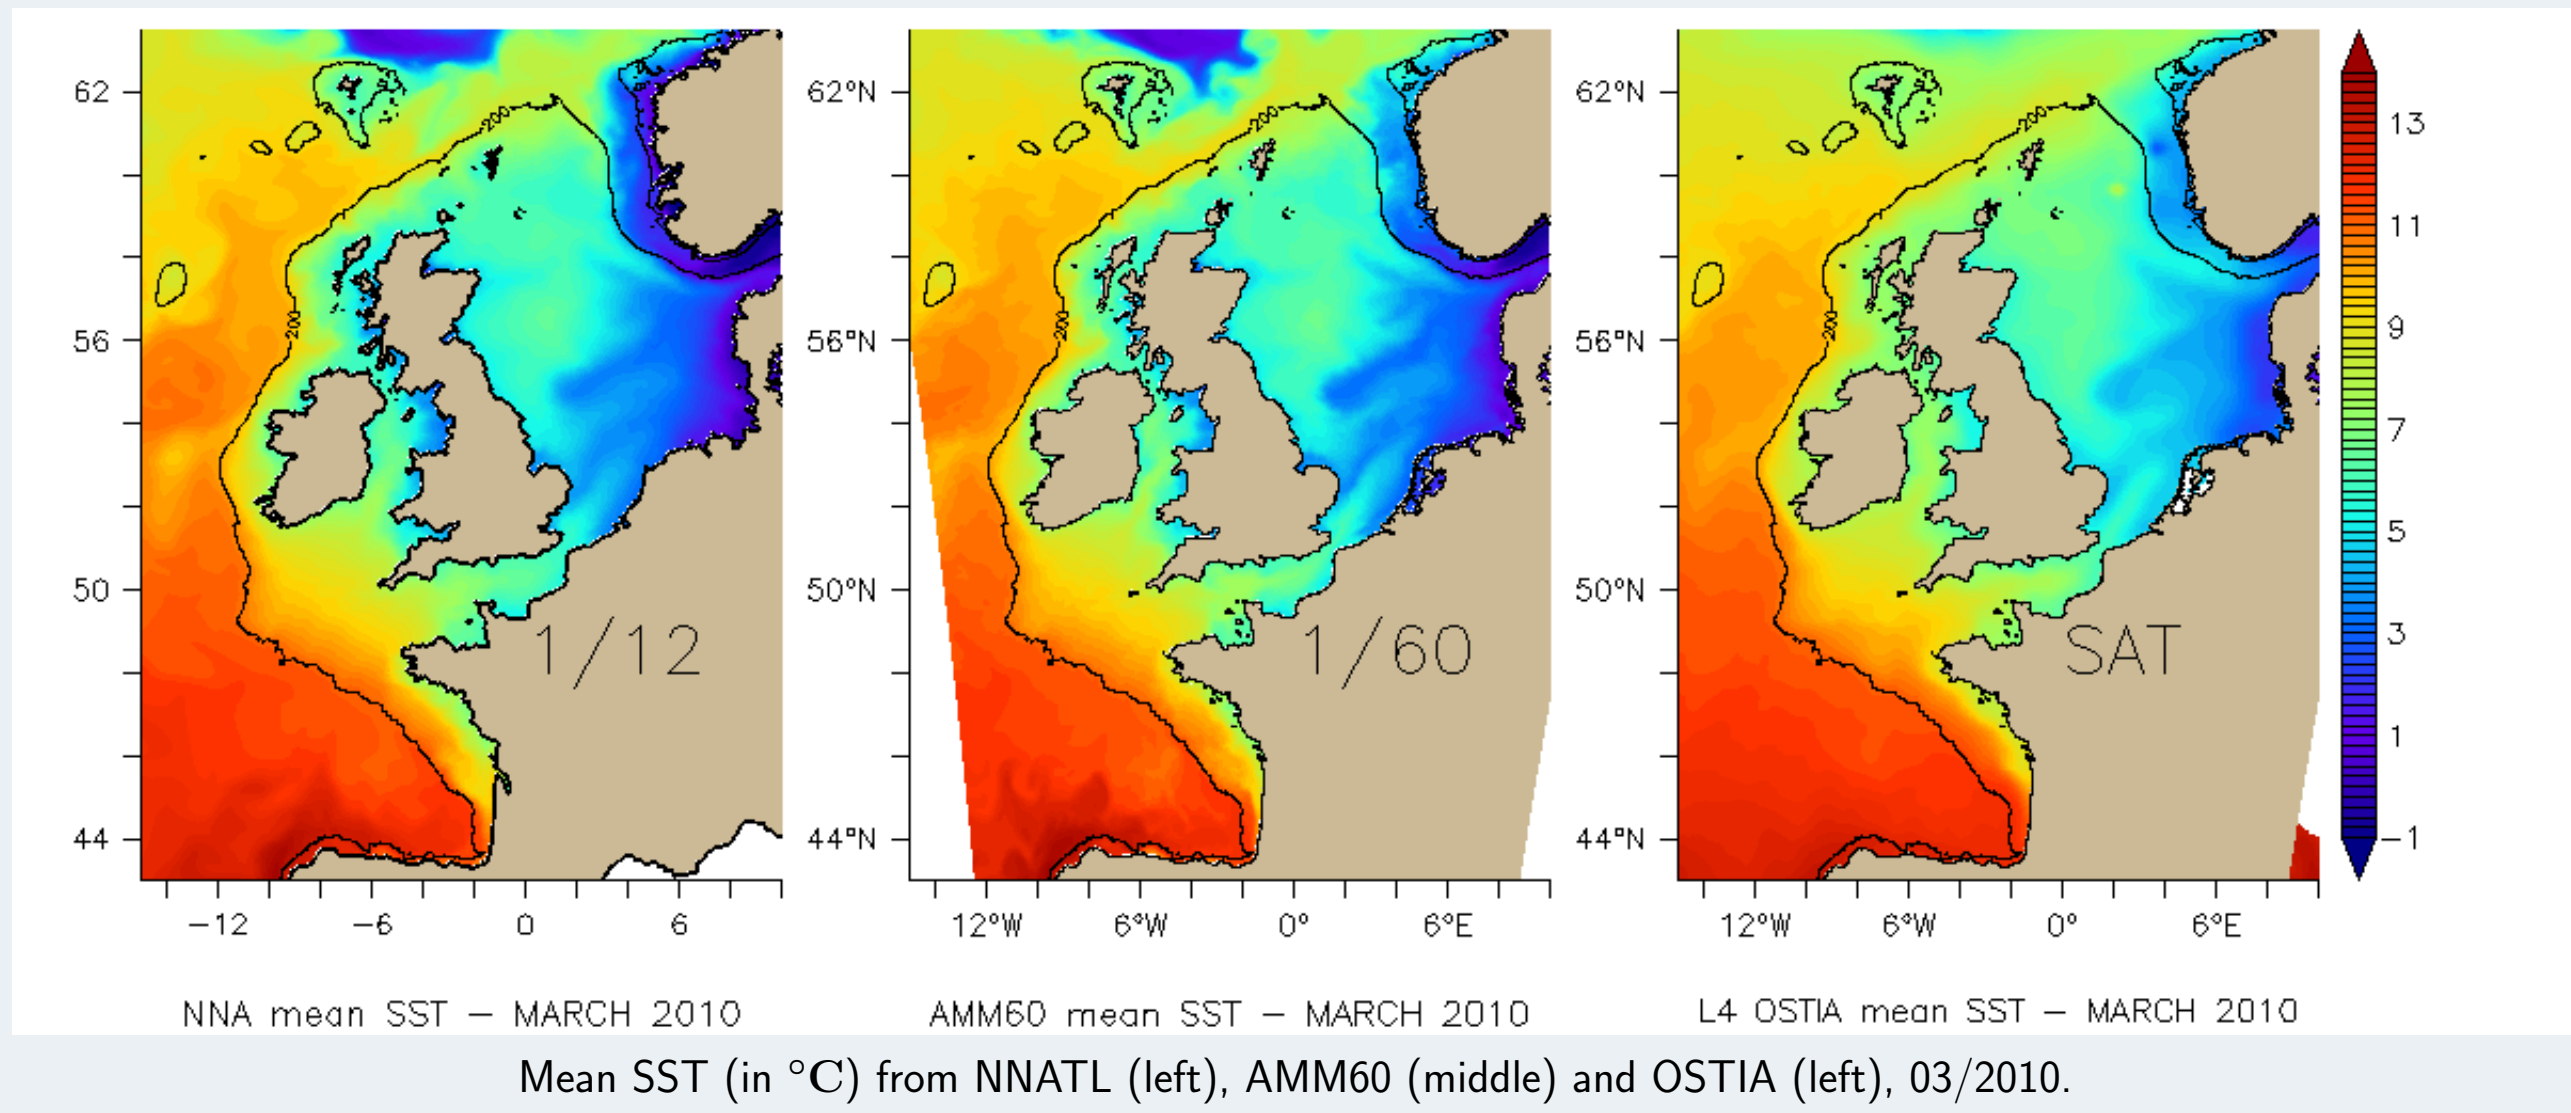

Left: Simulated amplitude of the M2 constituent (dashed line). Crosses show the amplitude simulated at tide gauge locations. Right: Simulated amplitude of the M2 constituent (dashed line). Crosses show the amplitude measured at tide gauge locations.

### 2) Assessment of the SST fields

- The SST is correctly reproduced by AMM60, in agreement with satellite data:
  - Warm front at the shelf break
  - Intrusion of cold waters from the north of the domain and the Baltic Sea
- NNATL and AMM60 have similar patterns:
  - NNA forces AMM60 at the lateral boundaries.
  - Surface forcings are from the same source (ERA interim).

*The model reproduces correctly the surface water masses. The forcings have a strong impact on the intruding water masses (cold water intrusion in the North of the domain). No bias is introduced by the increase in resolution.*

## Future work on high-frequency processes and other projects

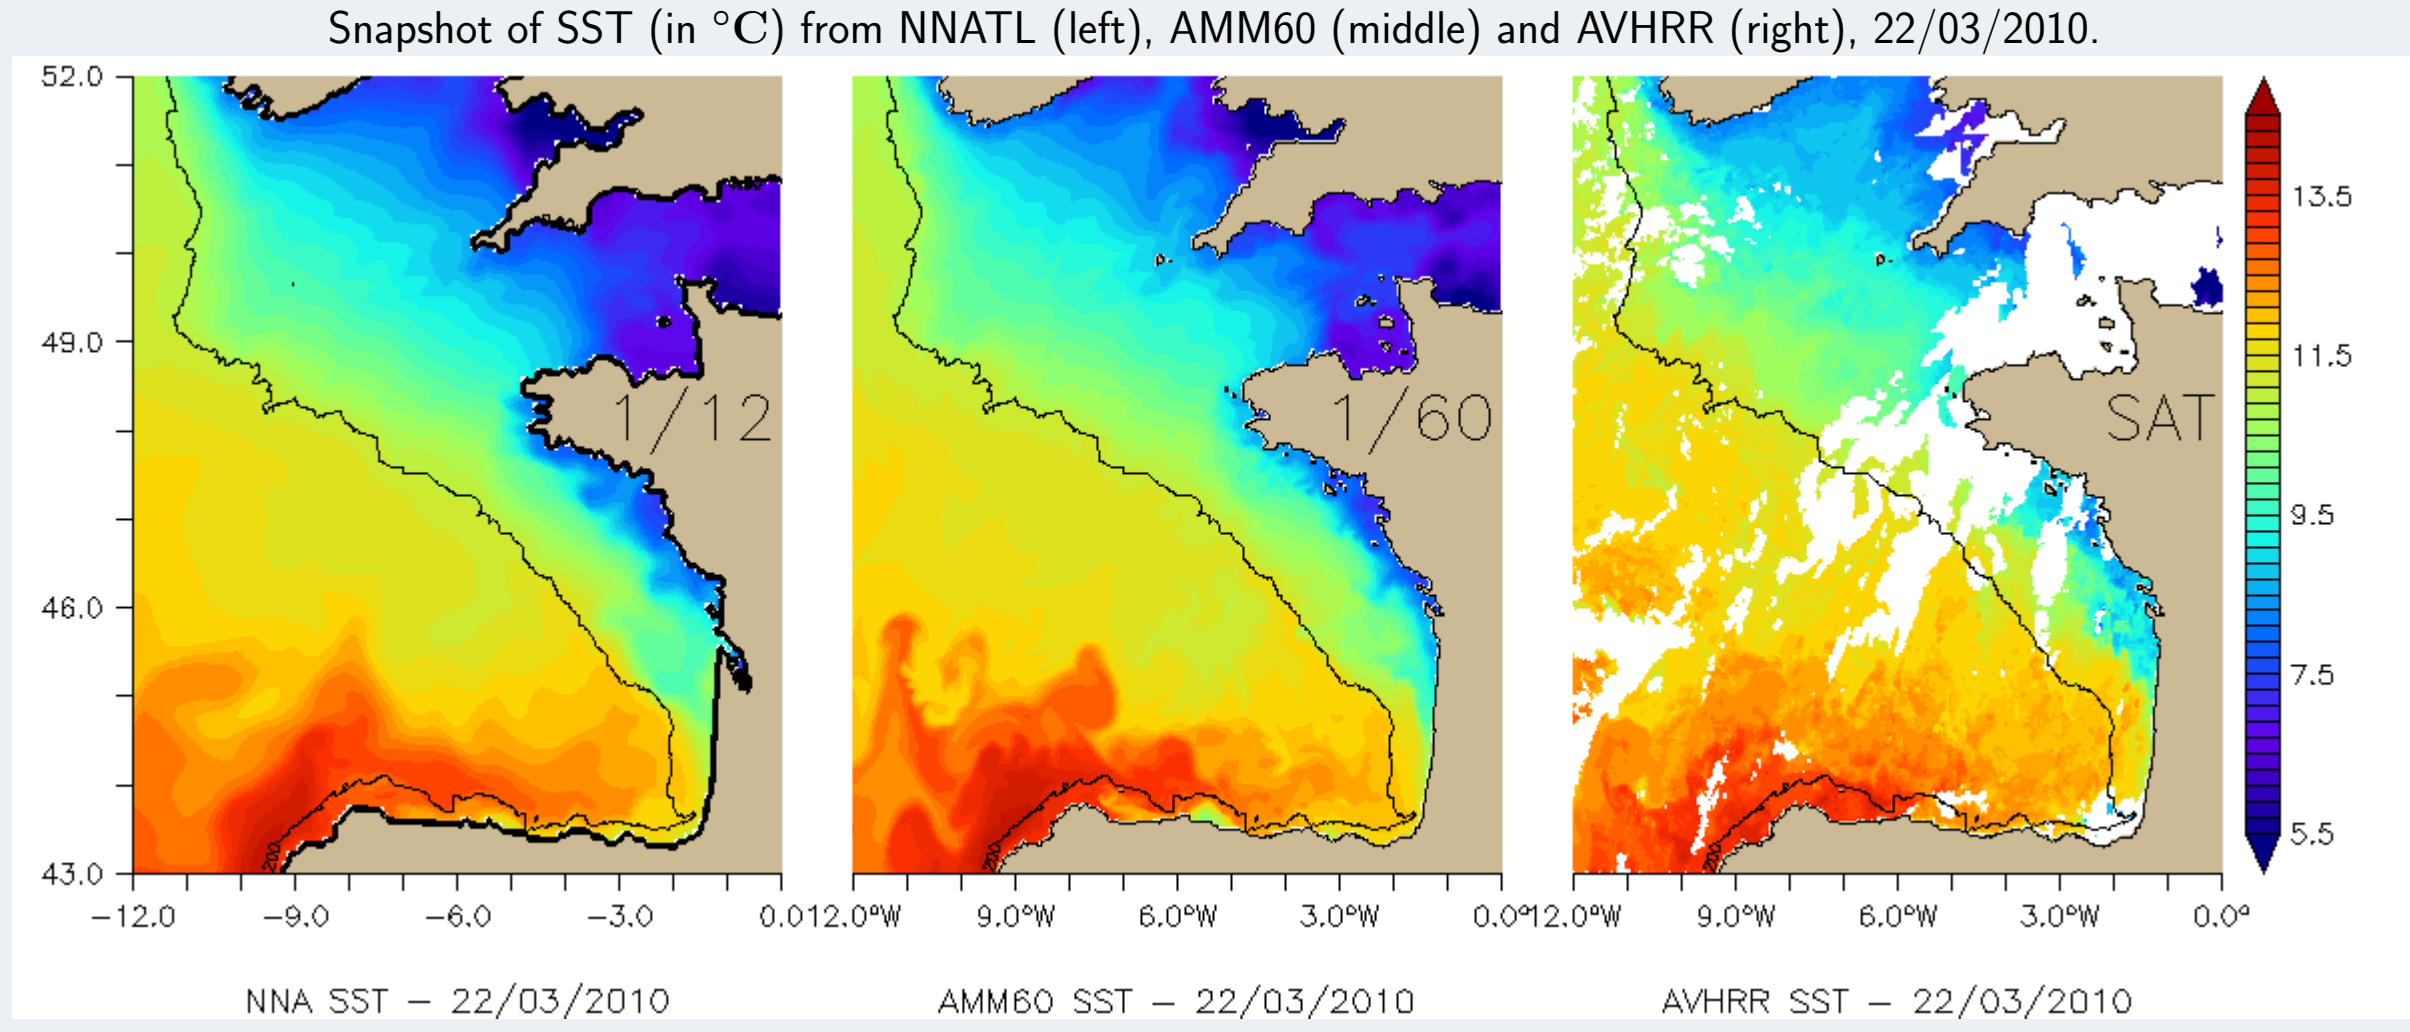

- About the observation of IT and mesoscale structures:
  - We will have new insight on the shelf/sea exchanges.
  - It allows combined data-model studies.
- Simulations on 2012-2014
  - Variability of ocean-shelf processes
  - FASTNet cruises (gliders, stations)
  - Model intercomparison (MITgcm)

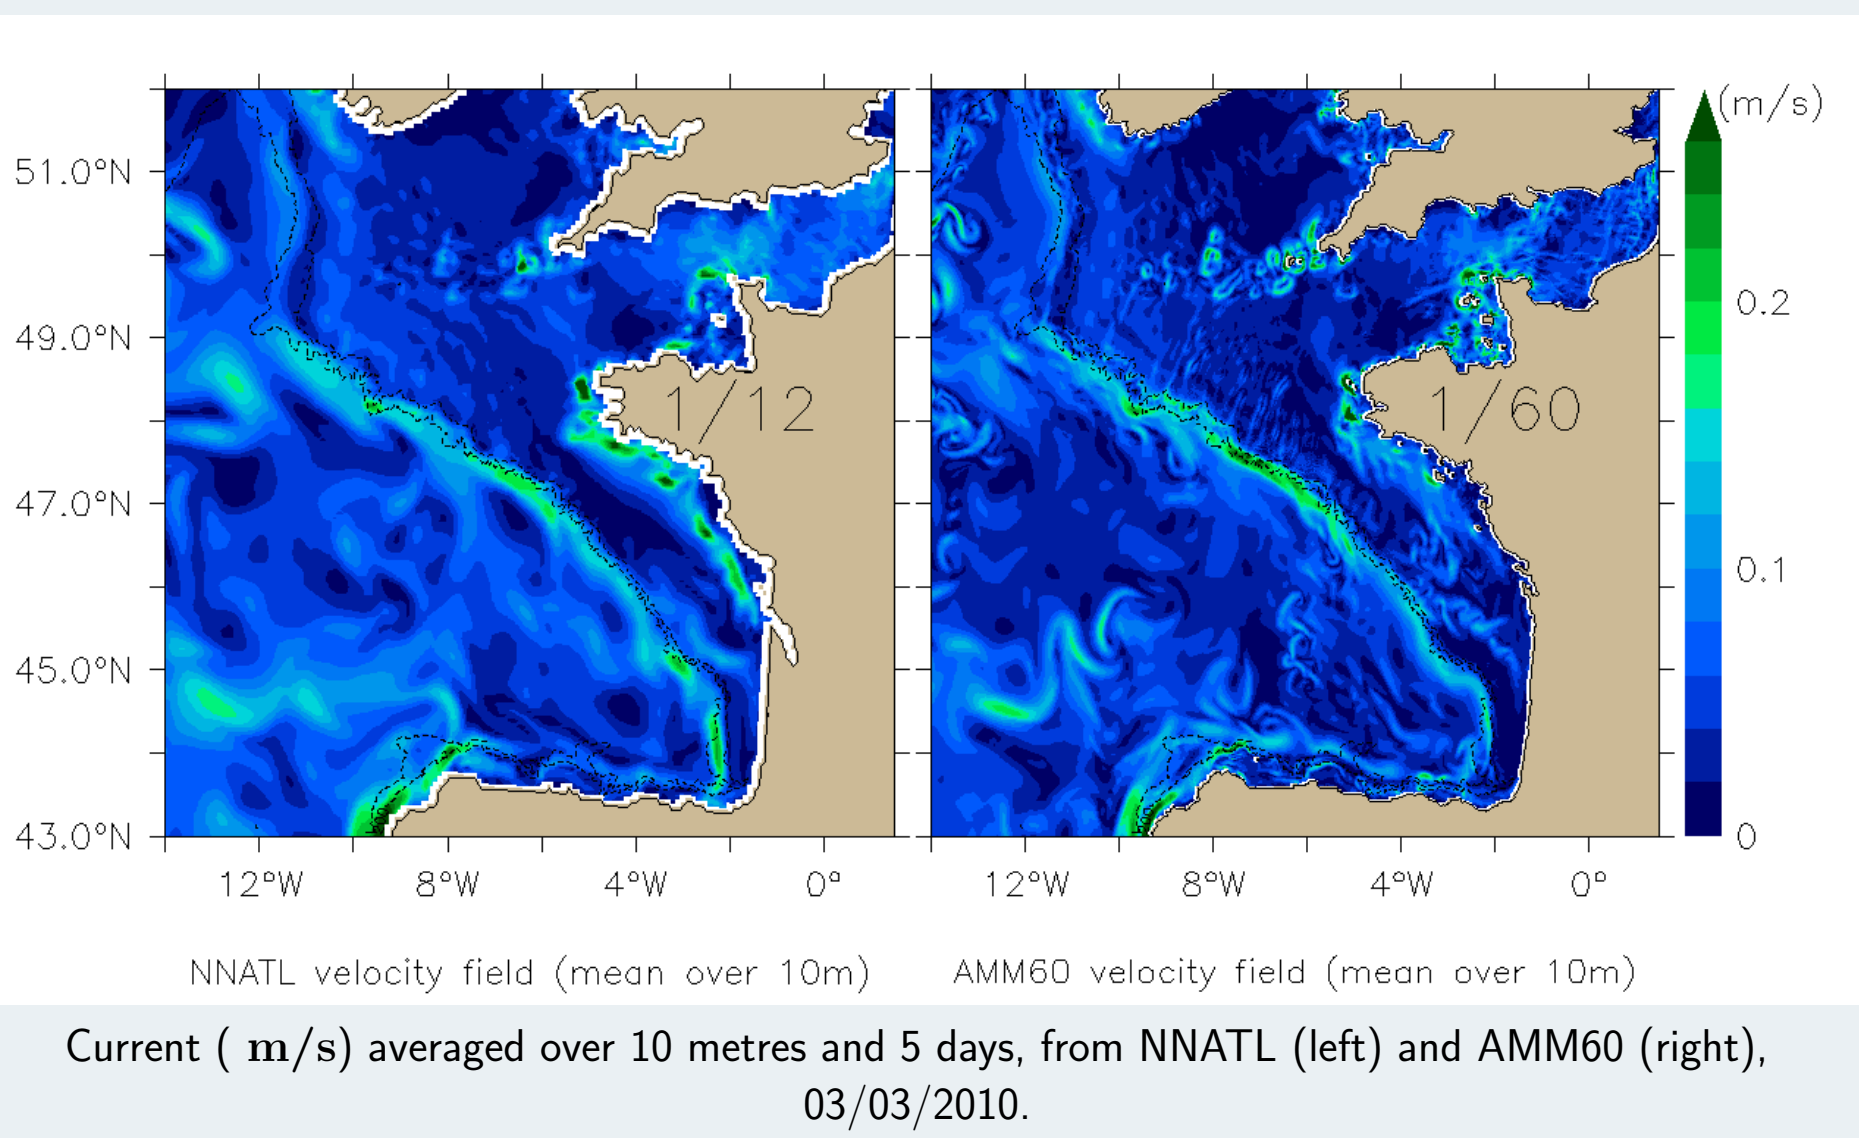

AMM60 is the precursor to UKO, a 1.5km configuration aimed at a fully coupled (air, land, sea) system. AMM60 or UKO will be evaluated as a possible successor to the NWS operational system. Development of UKO started in MYOCEAN-II and will continue in MYOCEAN-FO

## High-resolution processes

### 1) Mesoscale processes

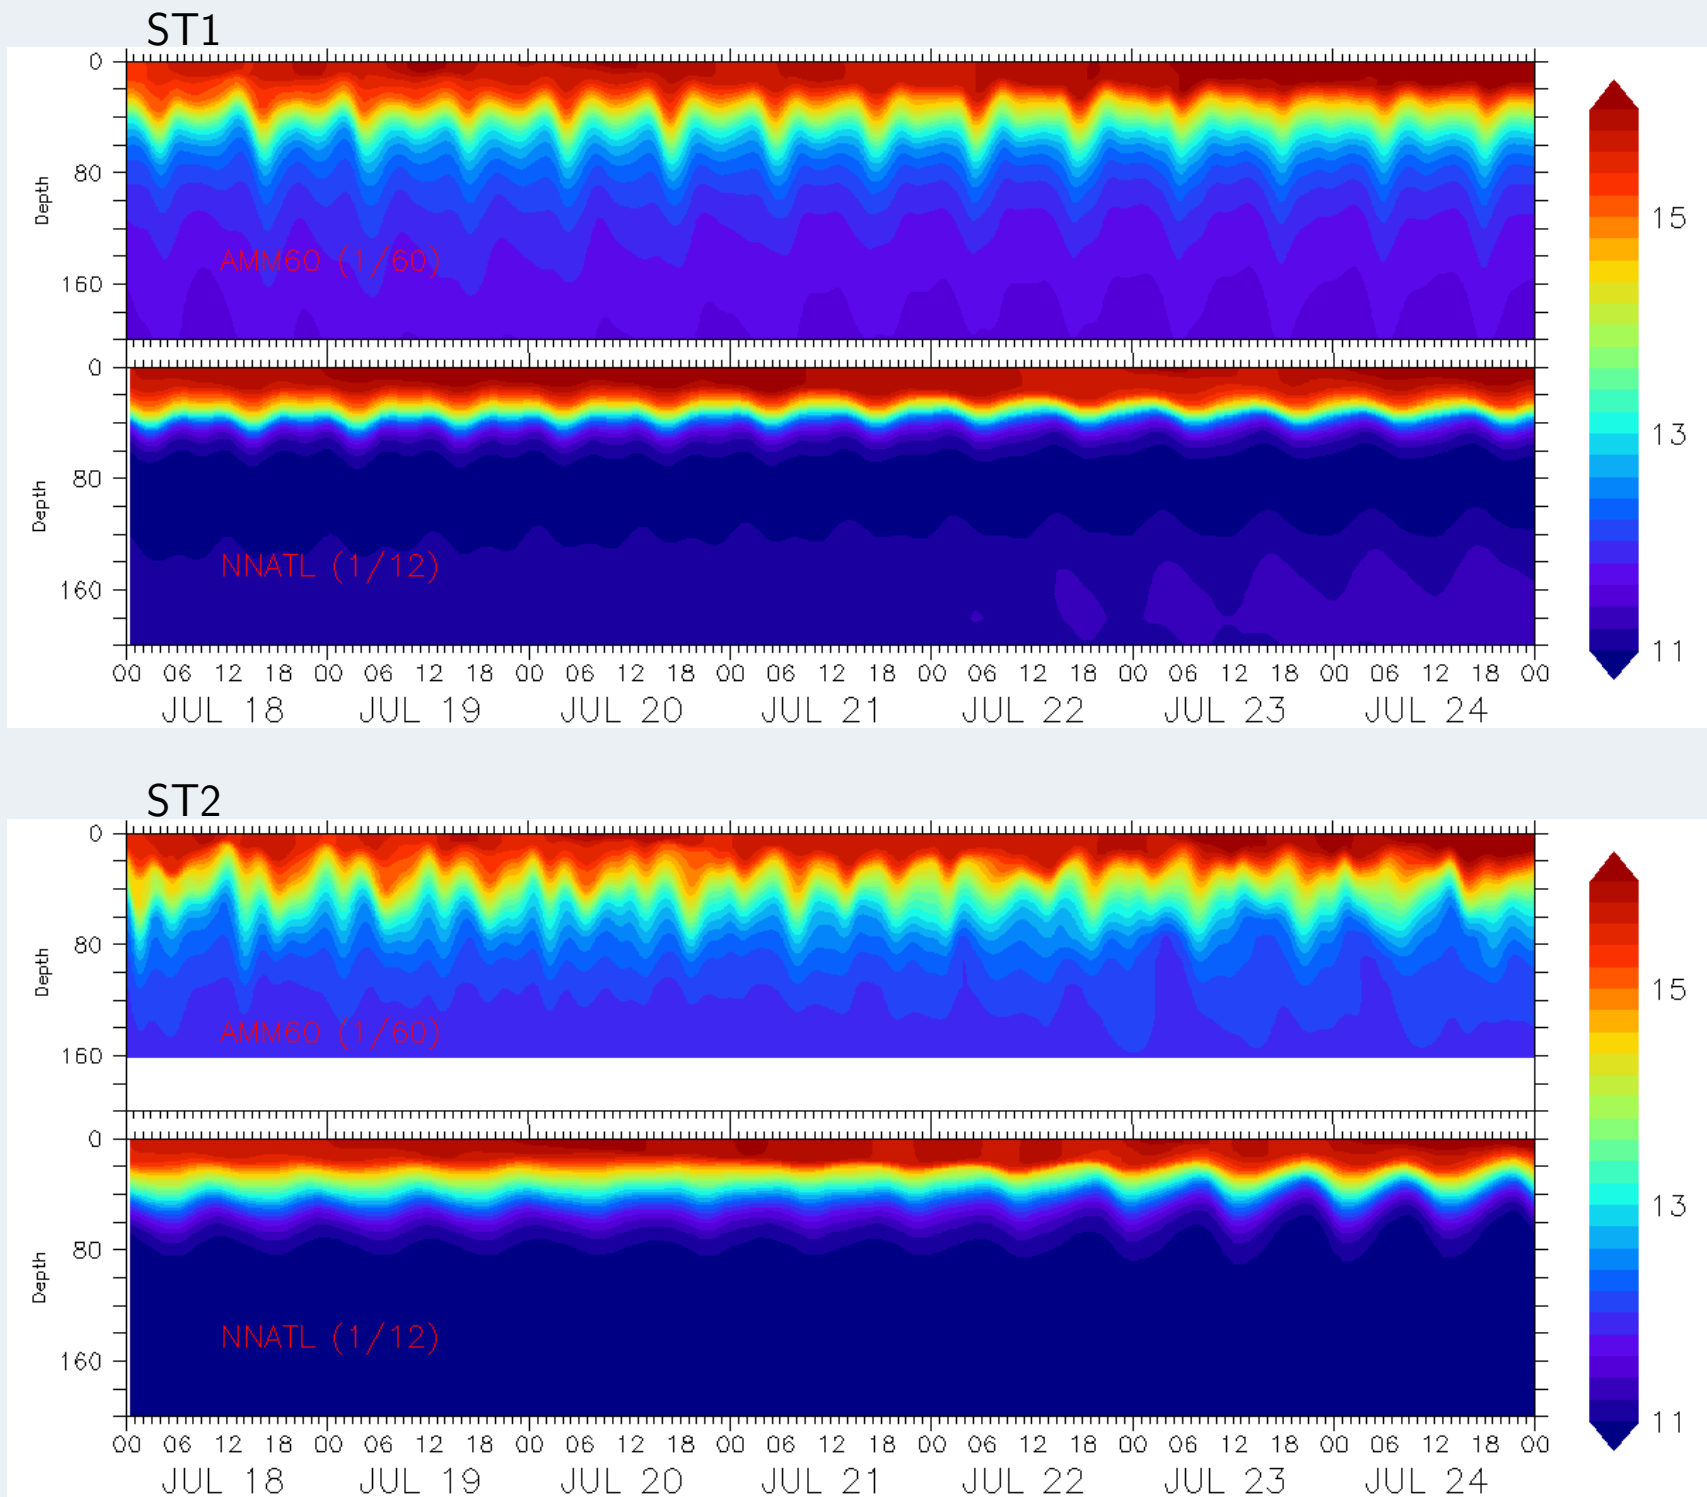

We observe the same general patterns in the 1/60° as in the 1/12° configuration, but with numerous eddies and filaments in AMM60: offshore, along the slope, and on the shelf.

*The presence of mesoscale structures on the shelf break and around banks will lead to more mixing and ocean-shelf exchange.*

### 2) Internal tides (IT)

Time series of temperature show the propagation of IT on the Celtic Sea, in both 1/12° and 1/60° configurations.

→ There are more high-frequency processes in AMM60 compared against NNA.

→ Deepening of the thermocline in AMM60, due to the propagation of IT.

*The high-resolution simulation reproduces more IT, which is likely to increase the vertical and cross-shelf mixing.*
