Multi-band observation of transient luminous events (TLEs) is one of the useful methodologies to be employed in sprite campaigns. Here, we show a method to estimate the Boltzmann vibrational temperature of N<sub>2</sub> (B<sup>3</sup>Π<sub>g</sub>) by analyzing the 630nm-filtered, N<sub>2</sub> 1P-filtered and 762 nm-filtered images of TLEs. Our advanced method is validated in comparison with derived relative vibrational distributions by sprite spectrum (Kanmae et al., 2007). The imager recorded N<sub>2</sub> 1P-filtered emission (I<sub>1P</sub>, 623 – 754 nm) of TLEs indicates the intensity of N<sub>2</sub> 1P Δv=3 and partial with Δv=2 where dominated emissions with upper state vibrational number v=4, 5 and 6, i.e., N<sub>2</sub> 1P (4, 2), (4, 1), (5, 2) and (6, 3). The imager recorded 630 nm-filtered emissions (I<sub>630</sub>) were contributed primarily from N<sub>2</sub> 1P (10, 7) with v=10 while N<sub>2</sub> 1P (3, 1) for 762 nm-filtered emissions (I<sub>762</sub>) with v=3. Hence, we calculated the emission ratios of I<sub>630</sub> to I<sub>1P</sub>, I<sub>630</sub> to I<sub>762</sub> and I<sub>762</sub> to I<sub>1P</sub>. The emission ratios of I<sub>630</sub> to I<sub>1P</sub>, I<sub>630</sub> to I<sub>762</sub> and I<sub>762</sub> to I<sub>1P</sub> also reflect the relative vibrational distributions of vibrational levels with LOW v=3 (I<sub>762</sub>), MIDDLE v=4, 5, 6 (I<sub>1P</sub>, 623 – 754 nm), and HIGH v=10 (I<sub>630</sub>). Therefore, we use the Boltzmann temperature for indicating the relative vibrational distributions of the specified group (LOW/MIDDLE/HIGH) of N<sub>2</sub> (B<sup>3</sup>Π<sub>g</sub>) vibrational levels. For ISUAL recorded sprites, the average brightness of N<sub>2</sub> 1P (I<sub>1P</sub>), 762 nm (I<sub>762</sub>) and 630 nm (I<sub>630</sub>) emission was 2.3, 0.6 and 0.02 MR. The N<sub>2</sub> (B<sup>3</sup>Π<sub>g</sub>) vibrational temperatures (T<sub>v</sub>) were estimated to be 2800 K, 3200 K and 4300 K for multi-band emission ratios of I<sub>630</sub>/ I<sub>1P</sub>, I<sub>630</sub>/ I<sub>762</sub> and I<sub>762</sub>/ I<sub>1P</sub>. For observed elves, the average brightness I<sub>1P</sub>, I<sub>762</sub> and I<sub>630</sub> were 170, 50 and 3 kR. The estimated T<sub>v</sub> values were 3700 K, 3700 K and 3800 K for ratios I<sub>630</sub>/ I<sub>1P</sub>, I<sub>630</sub>/ I<sub>762</sub> and I<sub>762</sub>/ I<sub>1P</sub>. For observed gigantic jets, the derived T<sub>v</sub> values were 3000 – 5000 K for a ratio I<sub>762</sub>/ I<sub>1P</sub>. Through N<sub>2</sub> (B<sup>3</sup>Π<sub>g</sub>) T<sub>v</sub> analyses from emission ratios of ISUAL multi-band observation, we derived the N<sub>2</sub> (B<sup>3</sup>Π<sub>g</sub>) vibrational temperature that ranges between 3000 and 5000 K or higher in TLEs. Accuracy and variations of derived N<sub>2</sub> (B<sup>3</sup>Π<sub>g</sub>) T<sub>v</sub> are also discussed while the relative population of vibrational levels in the Boltzmann equilibrium are also compared with past spectra observation. The details are shown in the publication (<https://doi.org/10.1029/2019JA027311>).
