²University of Bonn, Institute for Geosciences, Germany

³Deutscher Wetterdienst, Offenbach, Germany

Goal: Assess the potential for a future reanalysis system at the sub-kilometer scale.

Important steps towards the **sub-kilometer** resolution:

1. Characterize the land surface heterogeneity;
2. Understand the urban climate representation;
3. Assess the added value of the increase in resolution;
4. Improve the processes representation.

Area of interest:

Night image from NASA, zoom over Central Europe.

Test period: June 2019

- ▶ Highest temperatures recorded in the region.
- ▶ Stress conditions for both humans and agriculture.
- ▶ Importance of correct representation for forecasting purposes.
- ▶ Followed by a second heat wave (July 2019).
- ▶ Strong media impact.

North Rhine-Westphalia: Densely inhabited, high data availability, tuned model

Experiments:

Acronym	$\Delta x/y$	Type	n ^o days	Model specifics	Land use	Convection parametriza- tion
OPS	2.1 km	Free run	30	no urban ^a	Globcover ^a	ON ^a
D2_CORINE	2.1 km	Free run	30	no urban ^a	Corine	ON ^a
D2_URB	2.1 km	Free run	30	Urban scheme	Globcover ^a	ON ^a
D2_CORURB	2.1 km	Free run	30	Urban scheme	Corine	ON ^a
GLC_D500	500 m	Free run	30	no urban ^a	Globcover ^a	OFF
COR_D500	500 m	Free run	30	no urban ^a	Corine	OFF

Table: ^a this is the default option.

Method

Land Use representation: GlobCover vs corine

Non-interpolated GlobCover and Corine datasets:

(a) Globcover

(b) Corine

Legend: (green) High rise vegetation, (yellow) low rise vegetation, (gray) urban/industrial areas

Method

Urban land use within NRW in the D2.1

Land use fraction (within the grid-cell) for the 2.1 km resolution run, focus on North-Rhine Westphalia.

(c) Globcover

(d) Corine

Stations:

- ▶ Black dots: **DWD**, this is the official network with quality controlled stations.
- ▶ Green dots: **LANUV**, this is the regional network, which has not been controlled yet.

Urban stations are encircled in red.

Evaluation

Comparison with ground stations

8

Evaluation

Root Mean Square Error improvement w.r.t. default D2.1

Baseline process:

1. Urban core and rural area extension:
black boxes;
2. Select **no** urban grid-points;
3. Orography constrain: Rural points have
similar altitude to the urban core;
4. Rural points and urban core must have
roughly the same size

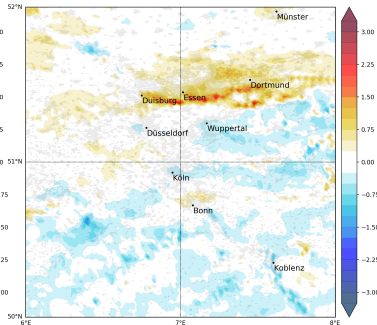

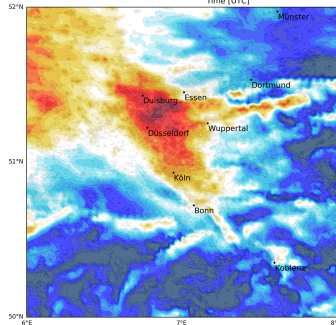

Use the spatial average value as subtraction
baseline

Results D2.1

UHI results: 25 June 03:40 UTC

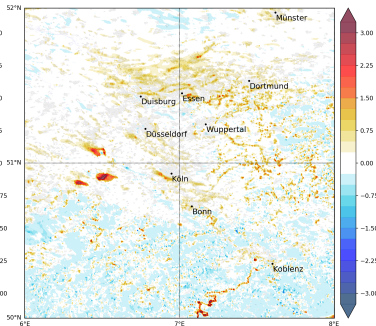

Baseline timeseries:
COR_D2 (blue) has a warmer baseline than the OPS (yellow) for the whole period.

Corine UHI (COR_D2, left) and difference between UHI (OPS-COR_D2, right): COR_D2 captures higher temperatures differences (w.r.t. rural areas) in the eastern part of the urban agglomeration (Dortmund, Essen).

Results D500

UHI results: 25 June 03:40 UTC

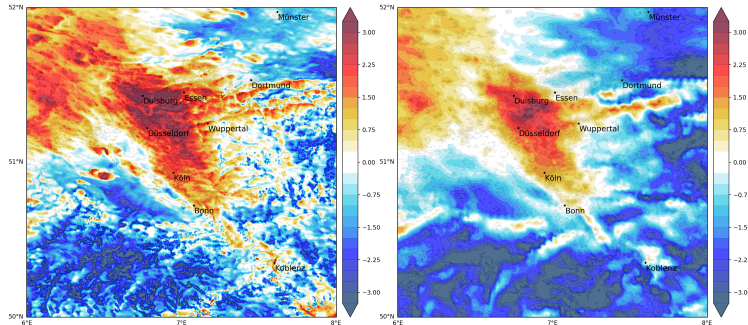

Baseline timeseries:
COR_500 (blue) has still a warmer baseline than GLC_500 (yellow) in the 500-m resolution

Corine UHI (COR_D500, left) and difference between UHI (GLC_D500-COR_D500, right): better LU representation in corine: e.g. smaller rivers are included (bottom right warm part), slightly higher temperatures in the new urban areas.

Results: comparison between resolutions

Qualitative comparison of the UHI results

Baseline timeseries:
warmer baselines w.r.t. the
operational settings (OPS),
up to 1.5 °C. The maxima
is during nighttime.

500-m Corine UHI
(COR_D500, left) and
2-km Corine UHI
(COR_D2, right): higher
UHI values in the 500-m
resolution, despite the
increase in the baseline
w.r.t. 2-km; better
representation of the
smaller UHI in the smaller
towns/cities of the region
(e.g. Koblenz, lower right).

Results D2.1

Diurnal evolution of UHI: Hovmöller diagram

Globcover

Corine

Work in progress

RADOLAN: 19 June 2019, 19 UTC Convective event

2019-06-19 19:00:00 UTC

Snapshot of the radar composite
(first 5 mins):
intense organized precipitation
moving north-eastward.

NB. 19 days into the simulation
(which is continuous).

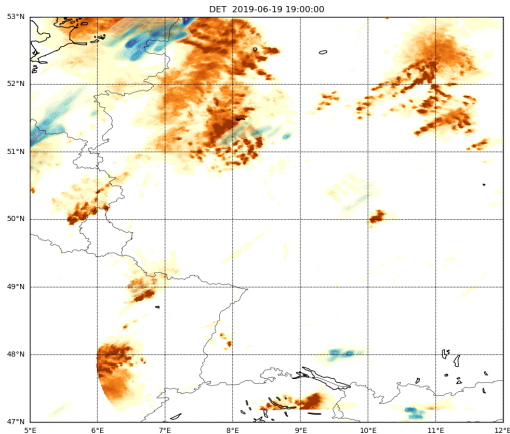

Work in progress

Qualitative comparison with radar composite: 19 June 2019, 19 UTC

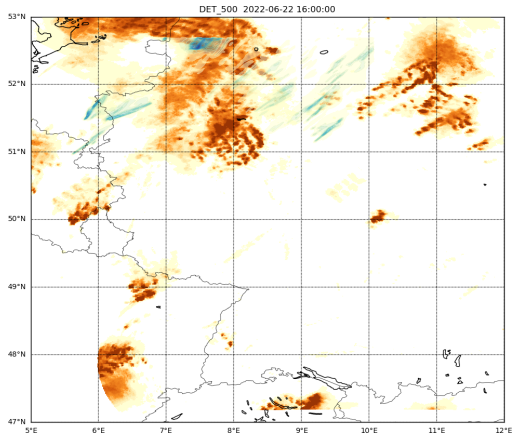

No improvement with increase in resolution: focus on the precipitation **location** (.. no need for the quantity as we are far off from reality)

OPS (2km)

GLC_500 (500 m)

the scales are similar in the colors (brown: radar, blue: model)

Conclusions:

- ▶ Generally, resolution improves the RMSE during the heat-wave period, especially in the LANUV network (mostly urban) and some of the DWD stations (mainly east and south west).
- ▶ UHI with corine is wider than with globcover, but the magnitude is similar. The UHI magnitude increases with the resolution, despite also the increase in the baseline.
- ▶ Corine baseline is consistently higher than globcover one.
- ▶ A better representation of the urban heat island (UHI) is still needed, as both globcover and corine peaks at sunset.

To **improve** our results and the urban representation, we look at:

1. increasing the spatial (and temporal) resolution;
2. improving the physical parameterizations of the urban areas.
3. running data assimilation with conventional observation and additional ones.
