# The North-Eastern German Lowlands TERENO Observatory

# General study design

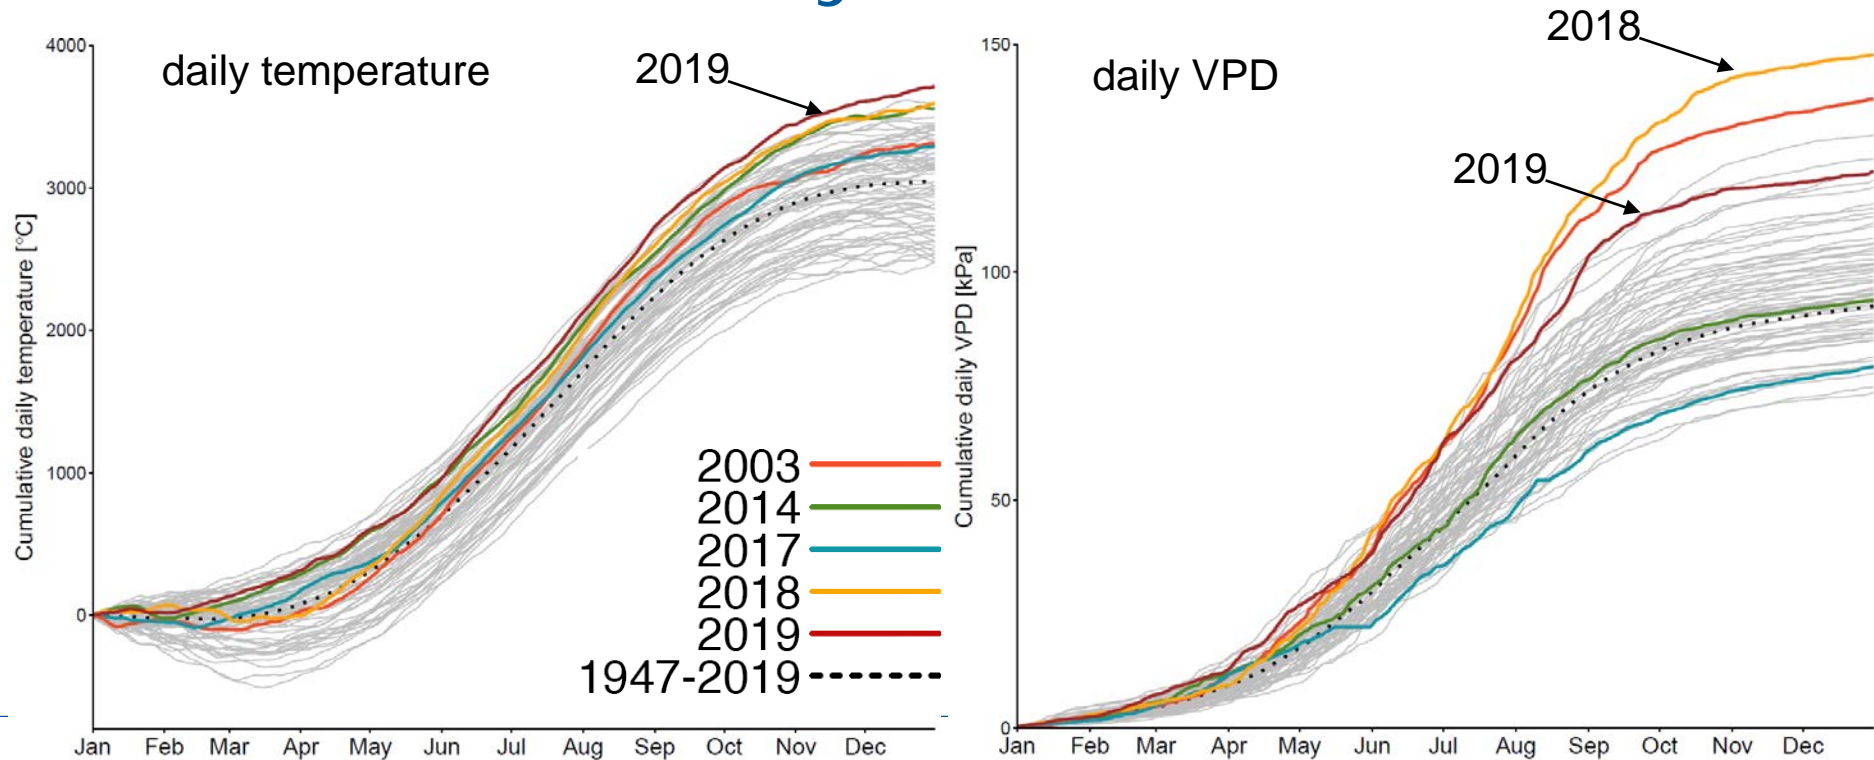

We compare upslope and downslope sites  
and different tree species/forest stands

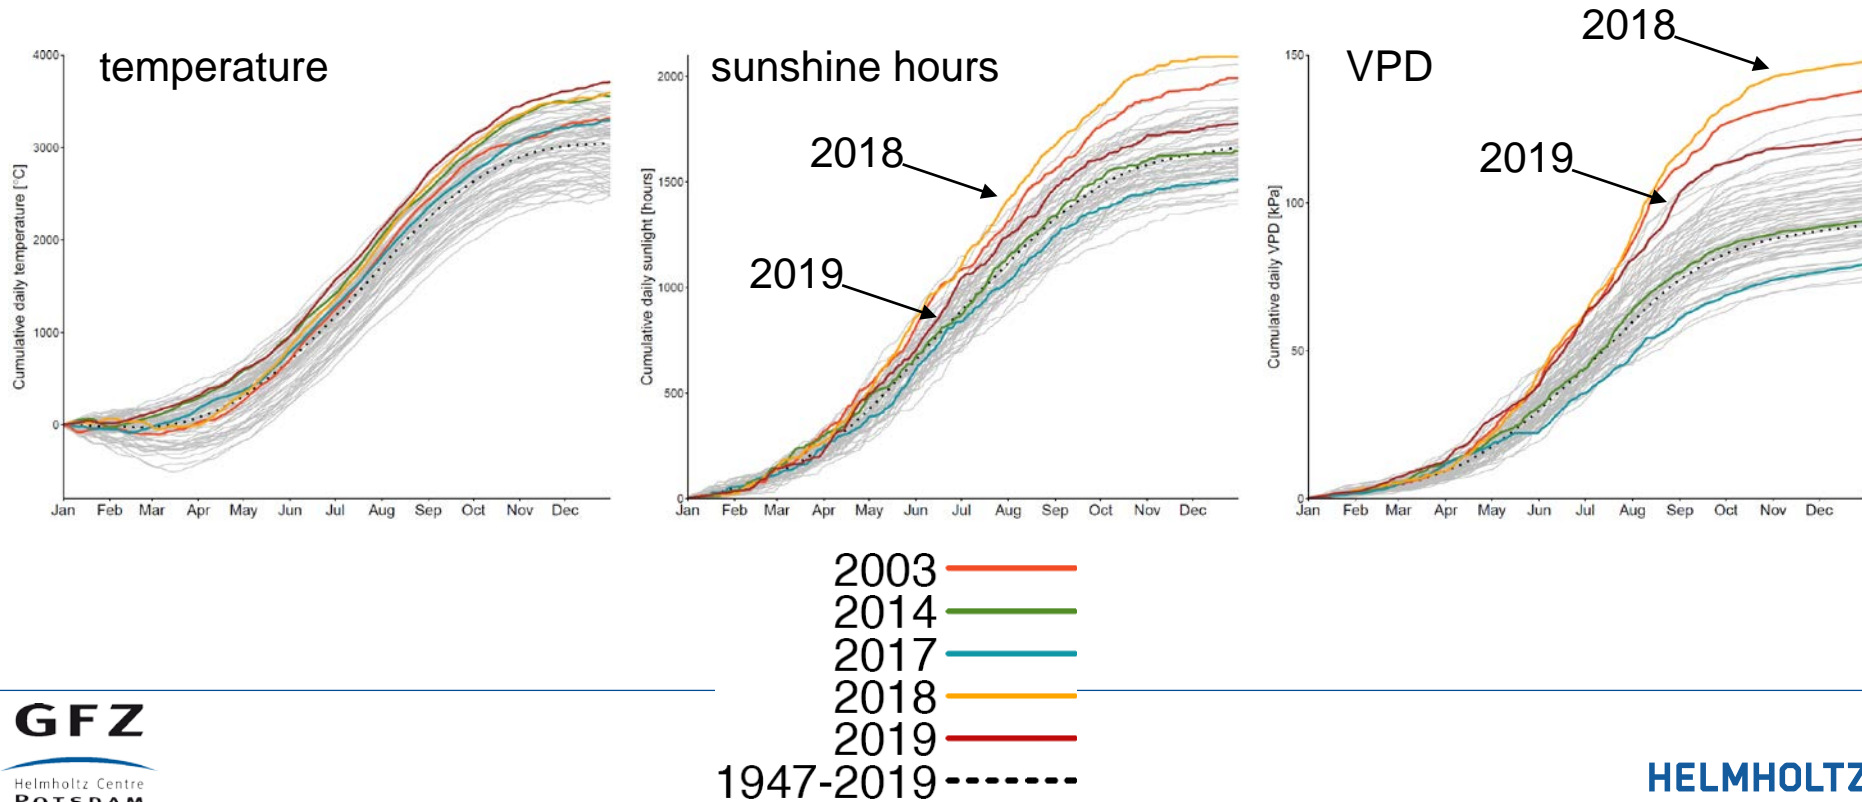

# Instrumentation

- Soil moisture sensors
- Observation wells
- Gravimeter
- Sap flow sensors
- Dendrometers

# How do 2018 and 2019 compare to other years?

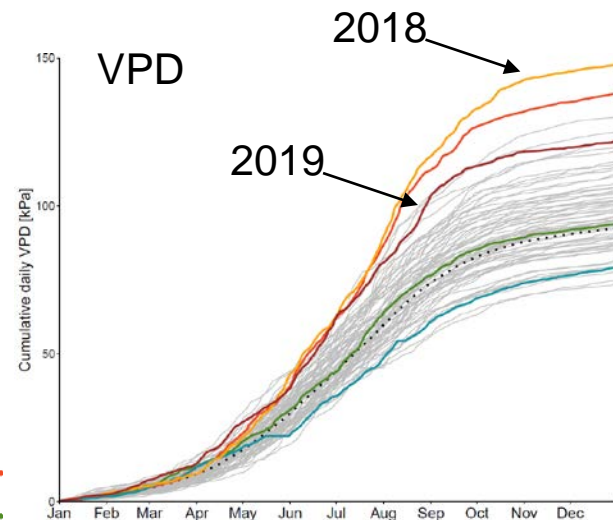

# How do 2018 and 2019 compare to other years?

# How do 2018 and 2019 compare to other years?

# How do 2018 and 2019 compare to other years?

- 2018 started wet and was then very dry
- The fall/winter of 2018/19 did not deliver sufficient recharge
- 2019 was hot, but had more rainfall than 2018

# Soil moisture

# Soil moisture

# Groundwater level dynamics

2018: big drawdown  
(luckily we started out wet)

Winter 18/19: too little recharge

# Groundwater and lake level fluctuations

© Peter Stueve

# Gravimetry: Total water storage changes

Other possible reasons for the huge gravity decrease:

- Instrumental issues (drift)
- Deep unsaturated zone
- Large-scale hydrology

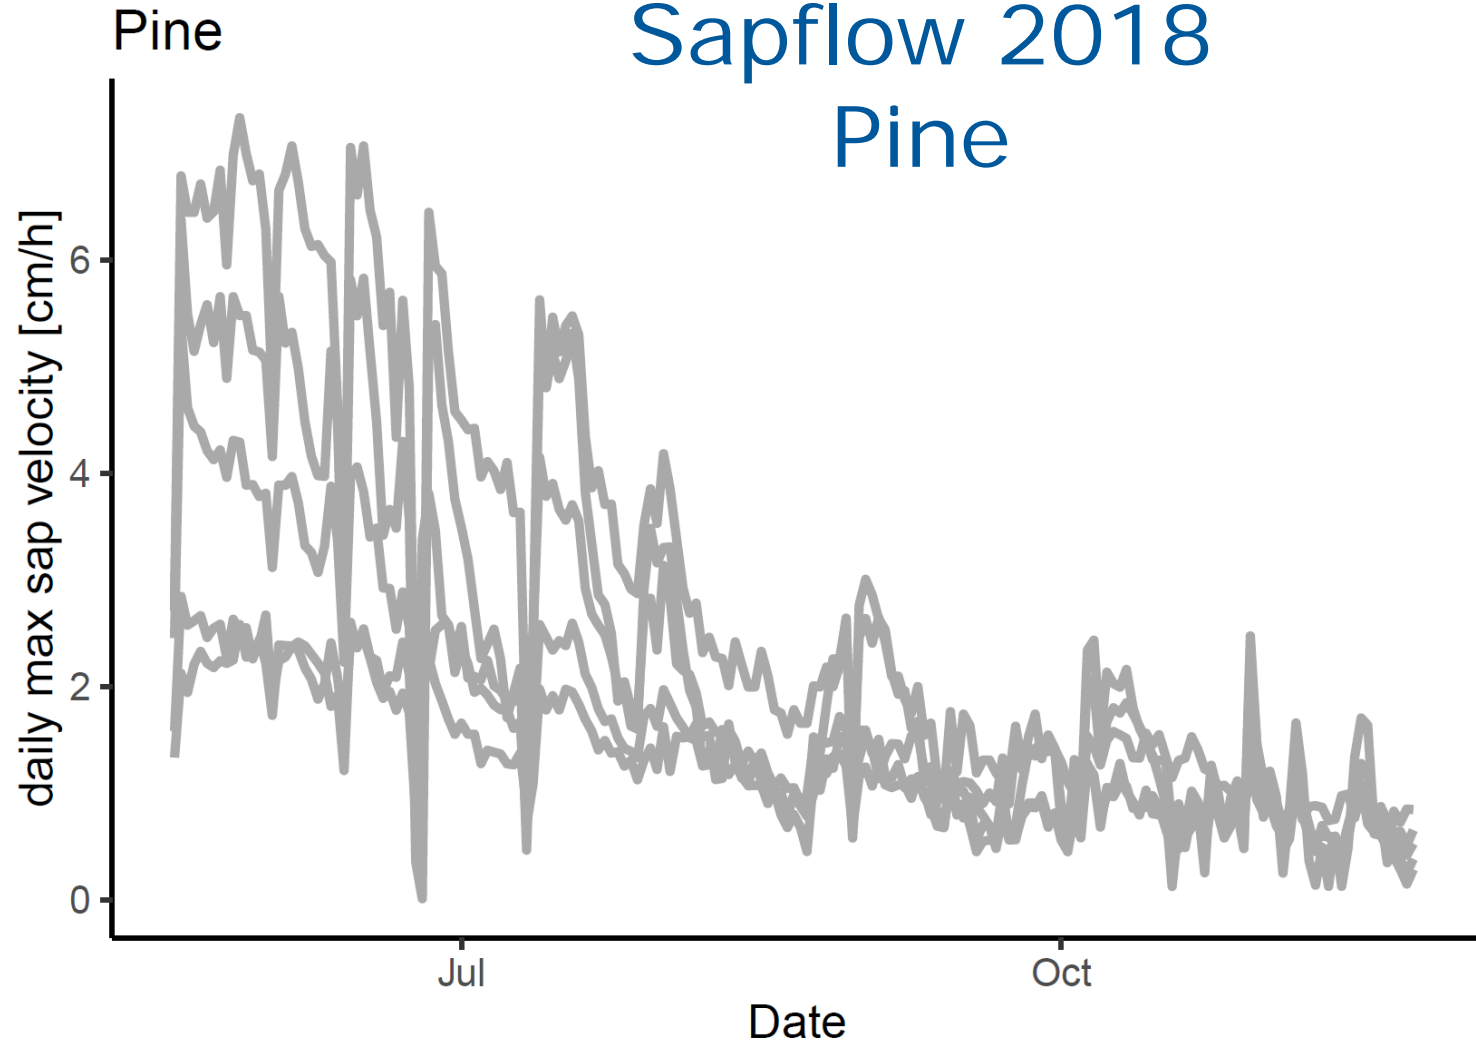

Two dry and hot summers  
– what does that mean for the trees?

# Dendrometer Measurements

# Tree growth

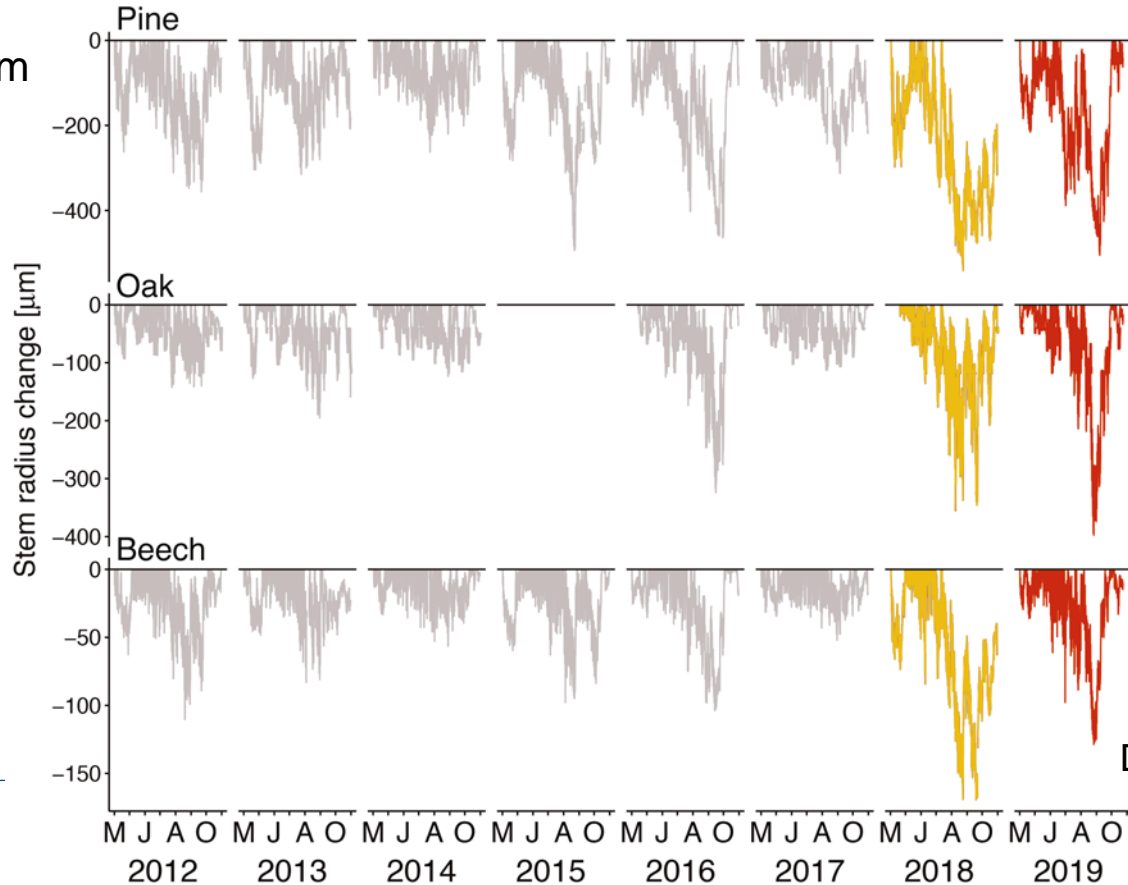

Reduced growth

Daniel Balanzategui

# Tree water deficit

based on tree stem  
shrinkage

Longer periods  
of tree water  
deficit

Daniel Balanzategui

# Summary

- 2018 and 2019 were exceptional years:
  - very dry and hot (2018), very hot (2019)
- Soil moisture and groundwater were depleted and did not recover over the winter
- All tree species showed signs of water stress
- Tree growth was negatively affected for all species, but least for oak
