Abstract

Nadir and Occultation for Mars Discovery (NOMAD) onboard ExoMars Trace Gas Orbiter (TGO) started the science measurements on 21 April 2018. We present results on the retrievals vertical profiles for several species in the Martian atmosphere from the first year measurements of the TGO/NOMAD. In particular, we present our progress on retrieving CO vertical profiles.

1. NOMAD Instrument

NOMAD, the “Nadir and Occultation for Mars Discovery” spectrometer suite [1], is part of the payload of the ExoMars Trace Gas Orbiter mission 2016. The instrument will conduct a spectroscopic survey of Mars’ atmosphere in the UV, visible and IR wavelengths covering the 0.2-0.65 and 2.3-4.3 μ m spectral ranges. NOMAD is composed of three channels: a solar occultation channel (SO) operating in the IR, a limb and nadir channel (LNO) also operating in the IR, and an ultraviolet/visible channel (UVIS) that can perform all observation modes. The spectral resolutions of SO and LNO is a significant improvement on previous infrared surveys of Mars ($\lambda/d\lambda\sim 15000$). Both SO and LNO consist of an

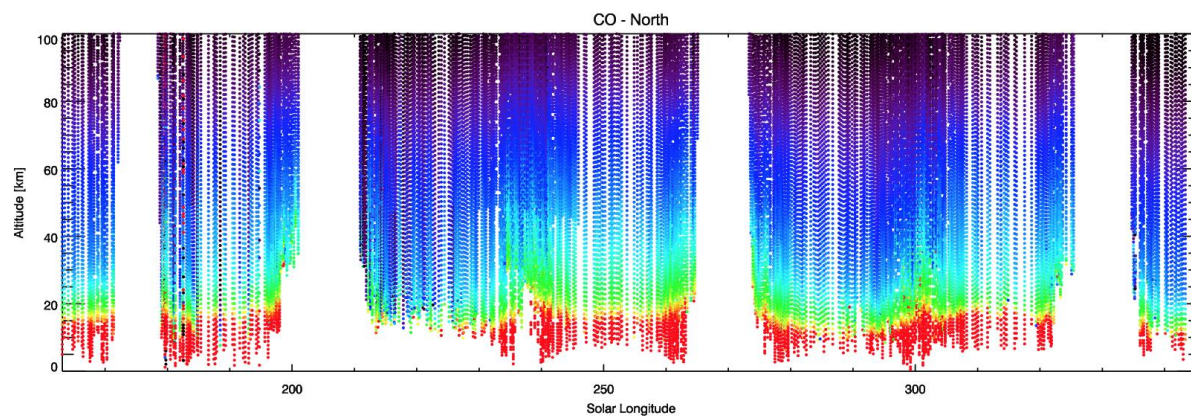

acousto-optic tunable filter (AOTF) in combination with an echelle grating. Several spectral ranges are measured simultaneously at a high spectral resolution, allowing for the study of different molecular species. The design of the three channels is fully described in [2] and [3].

2. Vertical Profile Retrievals

The vertical sampling rate of the SO channel is typically ~ 1 km, which provided an unprecedented vertical resolution from the surface up to ~ 200 km. ExoMars TGO has a ~ 2 hour orbital period, and the SO channel operates on $\sim 50\%$ of the potential occultations, which leads to great monitoring of the climatology. The calibration of SO is a collaborative exercise with retrievals, but inherits many of the techniques used for the SOIR/VEX instrument described in [4]. The retrievals are performed using the software ASIMUT developed at BIRA-IASB [5], which can use Optimal Estimation Method [6] among other algorithms to retrieve atmospheric profiles.

3. Discussion and Results

Carbon Monoxide is a non-condensable species playing a major role in the photochemical cycle of

CO₂. Local and seasonal variations are expected and will give valuable constraints for the dynamical processes in the Martian atmosphere. The 2-0 band of CO centered at 2.4 μ m is positioned in the SO orders 186-192 (4200-4350cm⁻¹). It is easily measurable in transmittances up to ~110km. In the figure above, we show that we have good observational coverage. In this presentation, we will talk about how we retrieve abundances from spectral absorption features, and try to isolate climatological effects from observational geometry.

ExoMars is a space mission of the European Space Agency (ESA) and Roscosmos. The NOMAD experiment is led by the Royal Belgian Institute for Space Aeronomy (IASB-BIRA), assisted by Co-PI teams from Spain (IAA-CSIC), Italy (INAF-IAPS), and the United Kingdom (Open University). This project acknowledges funding by the Belgian Science Policy Office (BELSPO), with the financial and contractual coordination by the ESA Prodex Office (PEA 4000103401, 4000121493), by the Spanish MICINN through its Plan Nacional and by European funds under grants ESP2015-65064-C2-1-P and ESP2017-87143-R (MINECO/FEDER), as well as by UK Space Agency through grant ST/P000886/1 and Italian Space Agency through grant 2018-2-HH.0. The IAA/CSIC team acknowledges financial support from the State Agency for Research of the Spanish MCIU through the 'Center of Excellence Severo Ochoa' award for the Instituto de Astrofísica de Andalucía (SEV-2017-0709). This work was supported by the Belgian Fonds de la Recherche Scientifique – FNRS under grant numbers 30442502 (ET_HOME) and T.0171.16 (CRAMIC) and BELSPO BrainBe SCOOP Project. US investigators were supported by the National Aeronautics and Space Administration.
